An increasing amount of researchers support reproducibility by including pointers and descriptions of datasets, software and methods in their publications. However, scientific articles may be ambiguous, incomplete and difficult to process by automated systems. In this paper we introduce RO-Crate, an open, community-driven, and lightweight approach to packaging research data with their metadata in a machine readable manner. Based on Schema.org annotations in JSON-LD, RO-Crate aims to establish best-practice for formal metadata description accessible and practical for use in a wide variety of situations.

An RO-Crate is a structured archive of all the items that contributed to a research outcome, including their identifiers, provenance, relations and annotations. As a general purpose packaging framework for data and their metadata, RO-Crate is used across multiple areas, including bioinformatics, digital humanities and regulatory submissions. By applying “just enough” Linked Data standards, RO-Crate simplifies the process of making research outputs FAIR.

Introduction

The move towards open science and open research practices has increased the demand for the publication of more artefacts of the research process [1]. This is particularly apparent in domains that rely on computational experiments; for example, the publication of software, datasets and records of the dependencies that such experiments rely on [2].

It is often argued that the publication of these assets, and specifically software [3] and data, should follow the The FAIR principles [4]; namely, that they are Findable, Accessible, Interoperable and Reusable. These principles are agnostic to the *implementation* strategy needed to comply with them. Hence, there has been an increasing amount of work in the development of systems and specifications that aim to fulfil these goals [5]. Important examples include data publication with rich metadata (e.g. Zenodo [6]), domain specific data deposition (e.g. PDB [7]) and following practices for reproducible research software [8] (e.g. use of containers).

These strategies are focused primarily on one *type* of artefact. To address this, [9] introduced the notion of **research objects** – *semantically rich aggregations of (potentially distributed) resources that provide a layer of structure on top of information delivered in a machine-readable format*. A research object combines the ability to bundle multiple types of artefacts together; for example, CSV files, code, examples, and figures. This provides a compelling vision as an approach for implementing FAIR. However, existing research object implementations require a large technology stack, are tailored to a particular platform and are also not easily usable by end-users.

To address this gap, a new community came together [10] to develop **RO-Crate** – an *approach to packaging and aggregating research artefacts with their metadata*. The aim of this paper is to introduce RO-Crate and assess it as a strategy for making multiple types of research artefacts FAIR. Specifically, the contributions of this paper are as follows:

1. an introduction to RO-Crate, its purpose and context;
2. a guide to the RO-Crate community and tooling;

3. and an exemplar usage of RO-Crate for different artefacts in different communities as well as its use as a connective tissue for such artefacts.

The rest of this paper is organised as follows. We first describe RO-Crate, the assumptions underlying it, and define RO-Crate technically and formally. We then proceed to introduce the community and tooling. We move to analyse RO-Crate with respect to usage in a diverse set of domains. Finally, we present related work and conclude with some remarks including RO-Crate highlights and future work.

RO-Crate

RO-Crate provides a lightweight approach to packaging research artifacts with their metadata. To illustrate this, let us imagine a research paper reporting on the sequence analysis of proteins obtained from an experiment on mice. The sequence output files, sequence analysis code, resulting data and reports summarising statistical measures or outputs are all important and inter-related research outputs, and consequently would ideally all be put in the same directory and accompanied with their corresponding metadata, but in reality some of the artefacts (e.g. data or software) will be external references, not necessarily captured in a FAIR way. This directory, along with the relationships between its constituent digital artefacts, is what the RO-Crate model aims to represent, linking together all the elements pertaining to an experiment and required for its reproducibility.

The question then arises as to how the directory with all this material should be packaged in a manner that is accessible and usable by others. By usable we mean not just readable by humans but programmatically accessible. A de facto approach to sharing collections of resources is through compressed archives (e.g. a zip file). This solves the problem of “packaging”, but it does not guarantee downstream access to all artefacts in a programmatic fashion, or the role of each file in that particular research. This leads to the need for explicit metadata about the contents of the folder, describing and linking them together.

Examples of metadata descriptions across a [wide range of domains](#) abound within the literature, both in research data management (?cite) and within library and information systems (?cite). However, many of these approaches require knowledge of metadata schemas, particular annotation systems, or the use of obscure or complex software stacks. Indeed, particularly within research, these requirements have led to a lack of adoption and growing frustration with current tooling and specifications [11].

RO-Crate seeks to address this complexity by:

1. being easy to understand and conceptually simple;
2. providing a strong and opinionated guide regarding current best practices;
3. adopting software stacks that are widely used on the Web.

In the following sections we show how the RO-Crate specification and ecosystem achieve these goals, which concur in forming our definition of “lightweight”.

Conceptual Definition

A key premise of RO-Crate is the existence of a wide variety of resources on the Web that can help describe research. As such, RO-Crate relies on concepts from the Web, in particular that of Linked Data. Figure 1 shows on the main conceptual elements involved in an RO-Crate; on the top it shows the metadata elements while on the bottom the artefacts bundled and described by the RO-Crate.

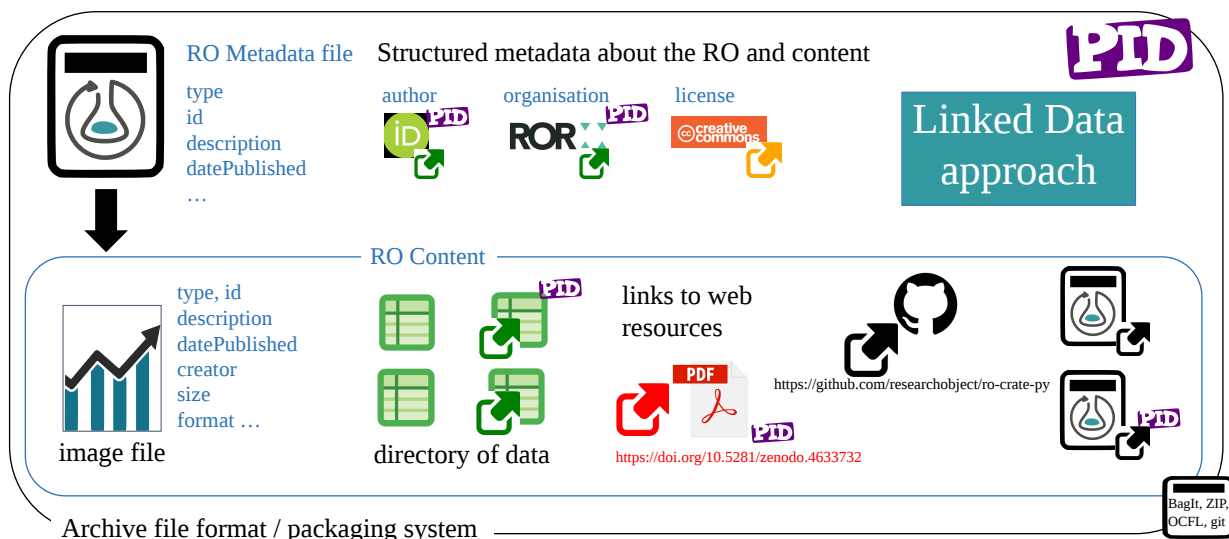

Figure 1: Conceptual overview of RO-Crate. A *Persistent Identifier* (PID) identifies a *Research Object* (RO), which is archived using BagIt[12], OCFL[13], git or ZIP. The RO is described within a , providing identifiers for authors using ORCID, organizations using ROR and licenses such as Creative Commons. The *RO-Crate content* is further described with its own metadata. Data can be embedded files and directories, as well as links to external web resources, PIDs and nested RO-Crates.

Linked Data as a core principle

Linked Data principles[14] (use of IRIs to identify resources (i.e. artefacts), resolvable via HTTP, enriched with metadata and linked to each other) are core to RO-Crate; therefore IRIs¹ are used to identify an RO-Crate package, its constituent parts and metadata descriptions, and the properties and classes used in the metadata.

Linked Data makes it possible for consumers to follow links for more (ideally both human- and machine-readable) information; as the RO-Crate relies on these principles, it can be sufficiently *self-describing* as artefacts can be interrelated using global identifiers, without needing to recursively fully describe every referenced artefact.

[PROPOSED REPHRASE ON PREVIOUS PAR] RO Crates are *self-described*; and follow the Linked Data principles to describe all of their resources in both human and machine readable manner. Hence, resources are identified using global identifiers; and relationships between two resources are defined with links.

The foundation on Linked Data and shared vocabularies also means multiple RO-Crates and other Linked Data resources can be indexed, combined, queried, integrated or transformed using existing Semantic Web technologies such as SPARQL and knowledge graph triple stores.

RO-Crate is a self-described container

An RO-Crate is defined as a self-described **Root Data Entity** that describes and contains *data entities*, which are further described using *contextual entities*. A **data entity** is a *file* (i.e., a set of bytes stored on disk somewhere) or a *directory* (i.e., dataset of named files) — while a **contextual entity** exists outside the information system (e.g. a Person) and it is defined by its metadata. The representation of a **data entity** as a set of bytes makes it possible to store a variety of research artefacts including not only data but also, for instance, software and text.

The Root Data Entity is a directory, the RO-Crate root, identified by the presence of the **RO-Crate Metadata File** (`ro-crate-metadata.json`). This is a JSON-LD file that describes the RO-Crate, its

content and related metadata using Linked Data. JSON-LD is an RDF serialization that has become popular as it is easy to read by humans while also offers some advantages for data exchange on the Internet (e.g. it removes some of the cross-domain restrictions that can be present with XML). JSON-LD is the preferred and widely supported format by RO-Crate tools and community.

The minimal [requirements for the root data entity metadata](#) are `name`, `description` and `datePublished`, as well as a contextual entity identifying its `license` — additional metadata is frequently added depending on the purpose of the particular RO-Crate.

RO-Crate can be stored, transferred or published in multiple ways, such as BagIt [12], Oxford Common File Layout [13] (OCFL), downloadable ZIP archives in Zenodo or through dedicated online repositories, as well as published directly on the Web, e.g. using GitHub Pages. Combined with Linked Data identifiers, this caters for a diverse set of storage and access requirements across different scientific domains, from metagenomics workflows producing hundreds of gigabytes of genome data to cultural heritage records with access restrictions for personally identifiable data.

Data Entities are described using Contextual Entities

RO-Crate distinguishes between [data and contextual entities](#) in a similar way to HTTP terminology's early attempt to separate *information* (data) and *non-information* (contextual) resources [16]. Data entities, are usually files and directories located by relative IRI references within the RO-Crate Root, but they can also be Web resources identified with absolute IRIs.

As both types of entities are identified by IRIs, their distinction is allowed to be blurry; data entities can be located anywhere and be complex, while contextual entities can have a Web presence beyond their description inside the RO-Crate. For instance <https://orcid.org/0000-0002-1825-0097> is primarily an identifier for a person, but secondarily also a web page that describes that person and their academic work.

Any particular IRI might appear as a contextual entity in one RO-Crate and as a data entity in another; their distinction lies in the fact that data entities can be considered to be *contained* or captured by the RO-Crate, while contextual entities mainly *explain* the RO-Crate and its entities. It follows that an RO-Crate should have one or more data entities, although this is not a formal requirement.

Figure 2 shows a UML view of RO-Crate, highlighting the different types of data entities and contextual entities that can be aggregated and related.

To further verify this idea, we have formalised the RO-Crate definition (see Appendix X). An important result of this exercise is that the underlying data structure of RO-Crate is a depth limited tree of 1 level. The formalisation also emphasises the *boundedness* of the structure; namely, the fact that elements are specifically identified as being either semantically *contained* by the RO-Crate (`hasPart`) or mainly referenced (`mentions`) and typed as *external* to the Research Object (Contextual Entities).

Technical implementation of the model

The RO-Crate conceptual model has been realised using JSON-LD and Schema.org in a prescriptive form as discussed in the best practice approach. This technical approach again caters for simplicity.

[JSON-LD](#) provides a way to express Linked Data as a JSON structure, where a *context* provides mapping to RDF properties and classes. While JSON-LD can't map arbitrary JSON structures to RDF, we found it does provide a good starting point for making a JSON-based language that is also interpretable as Linked Data.

However, JSON-LD alone, has too many degrees of freedom and hidden complexities for software developers to reliably produce and consume without specialized expertise or software libraries. A large part of the RO-Crate specification is therefore dedicated to describing JSON structures.

RO-Crate JSON-LD

RO-Crate mandates the use of [flattened, compacted JSON-LD](#) where a single `@graph` array contains all the data and contextual entities in a flat list. An example can be seen in the JSON-LD snippet below, describing a simple RO-Crate containing two datasets (data1.txt and data2.txt):

```

{ "@context": "https://w3id.org/ro/crate/1.1/context",
  "@graph": [
    { "@id": "ro-crate-metadata.json",
      "@type": "CreativeWork",
      "about": {"@id": "./"},
    },
    { "@id": "./",
      "@type": "Dataset",
      "hasPart": [
        {"@id": "data1.txt"},
        {"@id": "data2.txt"}
      ]
    },
    { "@id": "data1.txt",
      "@type": "File",
      "author": {"@id": "#alice"},
    },
    { "@id": "data2.txt",
      "@type": "File",
      "author": {"@id": "#alice"},
    },
    { "@id": "#alice",
      "@type": "Person",
      "name": "Alice",
    },
    { "@id": "http://sws.geonames.org/8152662/",
      "@type": "Place",
      "name": "Catalina Park"
    }
  ]
}

```

Figure X: Simplified RO-Crate JSON-LD showing the flattened compacted `@graph` array

It can be argued that this is a more graph-like approach than the tree structure JSON would otherwise invite, and which is normally emphasised as a feature of JSON-LD in order to “hide” its RDF nature.

However, we found that the use of trees for, e.g., a *Person* entity appearing as author of a *File* which nests under a *Dataset*, *hasPart*, counter-intuitively leads one to consider the JSON-LD as an RDF Graph, since an identified Person entity can then appear at multiple and repeated points of the tree (e.g. author of multiple files), necessitating node merging or duplication.

By comparison, a single flat `@graph` array approach means that applications can process and edit each entity as pure JSON by a simple lookup based on `@id`. At the same time, lifting all entities to the same level emphasizes Research Object’s principle that describing the context and provenance is just as important as describing the data.

RO-Crate reuses Schema.org, but provides its own versioned JSON-LD context, which has a similar flat list with the mapping from JSON-LD keys to their URI equivalents (e.g., `author` maps to <http://schema.org/author>). The rationale behind this decision is to support JSON-based RO-Crate applications that are largely unaware of JSON-LD, and thus still may want to process the `@context` to find Linked Data definitions of unknown properties and types. Not reusing the official Schema.org context means RO-Crate is also able to map in additional vocabularies where needed, namely the *Portland Common Data Model* (PCDM) [20] for repositories and Bioschemas [21] for describing computational workflows.

Similarly, rather than relying on implications from `"@type: @id"` annotations in the context, RO-Crate JSON-LD distinguishes explicitly between references to other entities (`{"id": "#alice"}`) and string values (`"Alice"`) - meaning RO-Crate applications can find the corresponding entity without parsing the `@context`.

RO-Crate Community

The RO-Crate conceptual model, implementation and best practices are developed by a growing community of researchers, developers and publishers. The RO-Crate community is a key aspect of its effectiveness in making research artefacts FAIR. Fundamentally, the community provides the overall context of the implementation and model and ensures its interoperability.

The RO-Crate community consists of:

1. a diverse set of people representing a variety of stakeholders;
2. a set of collective norms;
3. an open platform that facilitates communication (GitHub, Google Docs, monthly telcons).

People

The initial concept of RO-Crate was formed at the first Workshop on Research Objects ([RO2018](#)), held as part of the IEEE conference on eScience. This workshop followed up on considerations made at an [RDA meeting on Research Data Packaging](#) that found similar goals across multiple data packaging efforts [10]: simplicity, structured metadata and the use of JSON-LD.

An important outcome of discussions that took place at RO2018 was the conclusion that the original Wf4Ever Research Object ontologies [22], in principle sufficient for packaging research artefacts with rich descriptions, were, in practice, considered inaccessible for regular programmers (e.g. web developers) and in danger of being incomprehensible for domain scientists due to their reliance on Semantic Web technologies and other ontologies.

DataCrate [23] was presented at RO2018 as a promising lightweight alternative approach, and an agreement was made by a group of volunteers to attempt building “RO Lite” as a combination of DataCrate’s implementation and Research Object’s principles.

This group, originally made up of library and Semantic Web experts, has subsequently grown to include domain scientists, developers, publishers and more. This perspective of multiple views led to the specification being used in a variety of domains, from bioinformatics and regulatory submissions to humanities and cultural heritage preservation.

The RO-Crate community is strongly engaged with the European-wide biology/bioinformatics collaborative e-Infrastructure, ELIXIR, [24], along with European Open Science Cloud (EOSC) projects

including EOSC-Life and FAIRplus. RO-Crate has also established collaborations with Bioschemas, GA4GH, OpenAIRE and multiple H2020 projects.

A key set of stakeholders are developers; the RO-Crate community has made a point of attracting developers that are able to implement the specifications but, importantly, keeps “developer user experience” in mind. This means that the specifications are straightforward to implement and thus do not require expertise in technologies that are not widely deployed.

This notion of catering to “developer user experience” is an example of the set of norms that have developed and now define the community.

Norms

The RO-Crate community is driven by conventions or notions that are prevalent within it but not formalized. Here, we distil what we as authors believe are the critical set of norms that have facilitated the development of RO-Crate and contributed to the ability for RO-Crate research packages to be FAIR. This is not to say that there are no other norms within the community or that every one in the community holds these uniformly. Instead, what we emphasize is that these norms are helpful and also shaped by community practice.

1. Simplicity
2. Developer friendliness
3. Focus on examples and best practice rather than rigorous specification
4. Reuse “just enough” Web standards

A core norm of RO-Crate is that of **simplicity**, which sets the scene for how we guide developers to structure metadata with RO-Crate. We focus mainly on documenting simple approaches to the most common use cases, such as authors having an affiliation. This norm also influences our take on **developer friendliness**; for instance, we are using the Web-native JSON format, allowing only a few of JSON-LD’s flexible Linked Data features; moreover, the RO-Crate documentation is largely built up by **examples** showcasing **best practices**, rather than rigorous specifications. In a sense, we are allowed to do this by building on existing **Web standards** that themselves are defined rigorously, which we utilise “**just enough**” in order to benefit from the advantages of Linked Data (e.g. extensions by namespaced vocabularies), without imposing too many developer choices or uncertainties (e.g. having to choose between the many RDF syntaxes).

RO-Crate is not developed in a vacuum, and while the above norms alone could easily lead to the creation of “yet another” JSON format, we are also keeping the goal of **FAIR interoperability** of the captured metadata, and therefore follow closely FAIR best practices and current developments such as data citations, persistent identifiers, open repositories and recommendations for sharing research outputs and software.

Open Platforms

The critical infrastructure that enables the community around RO-Crate is the use of open development platforms. This underpins the importance of open community access to supporting FAIR. Specifically, it is difficult to build and consume FAIR research artefacts without being able to access the specifications, understand how they are developed, knowing about any potential implementation issues, and discuss usage to evolve best practices.

It was seen as more important to document real-life examples and best practices than to develop a rigorous specification. At the same time, we agreed to be opinionated on the syntactic form to reduce

the jungle of implementation choices; we wanted to keep the important aspects of Linked Data to adhere to the FAIR principles while retaining the option of combining and extending the structured metadata using the existing Semantic Web stack, not just build “yet another” standalone JSON format.

Further work during 2019 started adapting the DataCrate documentation through a more collaborative and exploratory *RO-Lite* phase, initially using Google Docs for review and discussion, then moving to GitHub as a collaboration space for developing what is now the RO-Crate specification, [maintained as Markdown](#) in GitHub Pages and published through Zenodo.

In addition to the typical Open Source-style development with GitHub issues and pull requests, the RO-Crate Community now has two regular monthly calls, a Slack channel and mailing list for coordinating the project, and many of its participants collaborate on RO-Crate at multiple conferences and coding events such as the ELIXIR BioHackathon. The community is jointly developing the RO-Crate specification and Open Source tools, as well as providing support and considering new use cases. The [RO-Crate Community](#) is open for anyone to join, to equally participate under a code of conduct, and currently has more than 40 members.

RO-Crate Tooling

The work of the community led to the development of a number of tools for creating and using RO-Crates. Table shows the current set of implementations. Reviewing this list, one can see that there are tools that support commonly used programming languages including Python, Javascript, and Ruby. Additionally, these tools can integrate with commonly used research environments; in particular, the command line (*ro-crate-html-js*). Furthermore, there are tools that cater to the end user (*Describe*, *Workflow Hub*). For example, Describe was developed to help researchers of the Australian [Criminal Characters project](#) annotate historical prisoner records, to gain greater insight into the history of Australia [25].

While the development of these tools is promising, our analysis of their maturity status shows that the majority of them are in the Beta stage. This is partly due to the fact that the RO-Crate specification itself only recently reached 1.0 status, in November 2019 [26]. Now that there is a fixed point of reference, and RO-Crate 1.1 (October 2020) [27] has stabilised based on feedback from application development, we expect to see a further increase in the maturity of these tools.

Given the stage of the specification, these tools have been primarily targeted to developers, essentially providing them with the core libraries for working with RO-Crates. Another target has been that of research data managers who need to manage and curate large amounts of data.

We argue that the adoption of simple web technologies in the RO-Crate specification has led to the rapid development of this wide variety of tools.

Tool Name	Targets	Language / Platform	Status	Brief Description
Describe [28]	Research Data Managers	NodeJS (Desktop)	RC	Interactive desktop application to create, update and export RO-Crates for different profiles
Describe Online [29]	Platform developers	NodeJS (Web)	Alpha	Web-based application to create RO-Crates using cloud storage
ro-crate-excel [30]	Data managers	JavaScript	Beta	Command-line tool to help create RO-Crates and HTML-readable rendering

Tool Name	Targets	Language / Platform	Status	Brief Description
ro-crate-html-js [31]	Developers	JavaScript	Beta	HTML rendering of RO-Crate
ro-crate-js [32]	Research Data Managers	JavaScript	Alpha	Library for creating/manipulating crates; basic validation code
ro-crate-ruby [33]	Developers	Ruby	Beta	Ruby library for reading/writing RO-Crate, with workflow support
ro-crate-py [34]	Developers	Python	Alpha	Object-oriented Python library for reading/writing RO-Crate
WorkflowHub [35]	Workflow users	Ruby	Beta	Workflow repository; imports and exports Workflow RO-Crate
Life Monitor [36]	Workflow developers	Python	Alpha	Workflow testing and monitoring service; Workflow Testing profile of RO-Crate
SCHeMa [37]	Workflow users	PHP	Alpha	Workflow execution using RO-Crate as exchange mechanism [38]
galaxy2cwl [39]	Workflow developers	Python	Alpha	Wraps Galaxy workflow as Workflow RO-Crate
Modern PARADISEC [40]	Repository managers	Platform	Beta	Cultural Heritage portal based on OCFL and RO-Crate
ONI express [41]	Repository managers	Platform	Beta	Platform for publishing data and documents stored in an OCFL repository via a web interface
ocfl-tools [42]	Developers	JavaScript (CLI)	Beta	Tools for managing RO-Crates in an OCFL repository
RO Composer [43]	Repository developers	Java	Alpha	REST API for gradually building ROs for given profile.
RDA maDMP Mapper [44]	Data Management Plan users	Python	Beta	Mapping between machine-actionable data management plans (maDMP) and RO-Crate [45]
Ro-Crate_2_maDMP [46]	Data Management Plan users	Python	Beta	Convert between machine-actionable data management plans (maDMP) and RO-Crate

Table 1: Applications and libraries implementing RO-Crate, targeting different types of users across multiple programming languages. Status is indicative as assessed by this work.

Using RO-Crate

RO-Crate is fundamentally an infrastructure to help build FAIR research artefacts. In other words, the key question is whether RO-Crate can be used to share and (re)use research artefacts. Here we look at three research domains where RO-Crate is being applied: Bioinformatics, Regulatory Science and Cultural Heritages. In addition, we note how RO-Crate may have an important role as part of machine-actionable data management plans.

Bioinformatics workflows

[WorkflowHub.eu](https://www.workflowhub.eu) is a European cross-domain registry of computational workflows, supported by European Open Science Cloud projects like [EOSC-Life](https://eosc-life.eu) and research infrastructures such as the pan-European bioinformatics network [ELIXIR](https://elixir-europe.org) [24]. As part of promoting workflows as reusable tools, WorkflowHub includes documentation and high-level rendering of the workflow structure independent of its native workflow definition format - the rationale being that a domain scientist looking for a particular computational analysis can browse all relevant workflows before narrowing down their workflow engine requirements. As such, the WorkflowHub is intended largely as a registry of workflows already deposited in repositories specific to particular workflow languages and domains, such as [UseGalaxy.eu](https://usegalaxy.eu) and [Nextflow nf-core](https://nf-co.re).

Being cross-domain, WorkflowHub has to cater for many different workflow systems. Many of these, for instance Nextflow and Snakemake, by virtue of their script-like nature, reference multiple neighbouring files typically maintained in a GitHub repository. This calls for a data exchange method that allows to keep related files together. WorkflowHub has tackled this problem by adopting RO-Crate as the packaging mechanism [47], typing and annotating the constituent files of a workflow and — crucially — marking up the workflow language, as many workflow engines use common file extensions like `*.xml` and `*.json`. Workflows are further described with authors, license, diagram previews and a listing of their inputs and outputs. RO-Crates can thus be used for interoperable deposition of workflows to the WorkflowHub, but are also used as an archive for downloading workflows, embedding metadata registered with the WorkflowHub entry and translated workflow definitions such as abstract Common Workflow Language files and diagrams [48].

RO-Crate acts therefore as an interoperability layer between registries, repositories and users in WorkflowHub. The iterative development between WorkflowHub developers and the RO-Crate community heavily informed the creation of the Bioschemas [21] profile for [Computational Workflows](https://bioschemas.org), which again informed the [RO-Crate 1.1 specification on workflows](https://rocrate.org/docs/rocrate-specification-on-workflows) and led to the RO-Crate Python library [34] and WorkflowHub's [Workflow RO-Crate profile](https://workflowhub.eu), which, in a similar fashion to RO-Crate itself, recommends which workflow resources and descriptions are required. This co-development across project boundaries exemplifies the drive for simplicity and for establishing best practices.

While RO-Crates in WorkflowHub so far have been focused on workflows that are ready to be run, they are now moving into the development of a *Workflow Run RO-Crate profile* for the purposes of benchmarking, testing and executing workflows. As such, RO-Crate serves as container of both a *workflow definition* that may be executed and of a particular *workflow execution with test results*. This profile is a continuation of our previous work with capturing workflow provenance in a Research Object in CWLProv [49] and TavernaPROV [50], but rather than detailing every task execution in PROV with all intermediate data, this profile will focus on a [schema.org provenance](https://schema.org/provenance) of the input/output boundary of the overall workflow execution. This *Level 1 workflow provenance* [49] can be expressed generally across workflow languages or engine types, with the option of more detailed provenance traces as separate resources in the RO-Crate.

WorkflowHub has recently enabled minting of DOIs for registered workflows, e.g. `10.48546/workflowhub.workflow.56.1` [51], lowering the barrier for citing workflows as computational methods along with their FAIR metadata – captured within an RO-Crate.

The value of computational workflows, however, is potentially undermined by the “collapse” over time of the software and services they depend upon: for instance, software dependencies can change in a non-backwards-compatible manner, or active maintenance may cease; an external resource, such as a reference index or a database query service, could shift to a different URL or modify its access protocol; or the workflow itself may develop hard-to-find bugs as it is updated. This can take a big toll on the workflow's reusability and on the reproducibility of any processes it evokes.

For this reason, WorkflowHub is complemented by a monitoring and testing service called LifeMonitor[36], also supported by EOSC-Life. LifeMonitor’s main goal is to assist in the creation, periodic execution and monitoring of workflow tests, enabling the early detection of software collapse in order to minimise its detrimental effects. The communication of metadata related to workflow testing is achieved through the adoption of a [Workflow Testing RO-Crate profile](#) stacked on top of the *Workflow RO-Crate* profile. This further specialisation of Workflow RO-Crate allows to specify additional testing-related entities (test suites, instances, services, etc.), leveraging [RO-Crate’s extension mechanism](#) through the addition of terms from custom namespaces.

In addition to showcasing RO-Crate’s extensibility, the testing profile is an example of the format’s flexibility and adaptability to the different needs of the research community. Though ultimately related to a computational workflow, in fact, most of the testing-specific entities are more about describing a protocol for interacting with a monitoring service than a set of research outputs and its associated metadata. Indeed, one of LifeMonitor’s main functionalities is monitoring and reporting on test suites running on existing CI services, which is described in terms of service URLs and job identifiers in the testing profile. In principle, in this context, data could disappear altogether, leading to an RO-Crate consisting entirely of contextual entities. Such an RO-Crate acts more as an exchange format for communication between services (WorkflowHub and LifeMonitor) than as an aggregator for research data and metadata, providing a good example of the format’s high versatility.

Regulatory Sciences

[BioCompute Objects](#) (BCO) [52] is a community-led effort to standardise submissions of computational workflows to biomedical regulators. For instance, a genomics sequencing pipeline, as part of a personalised cancer treatment study, can be submitted to the US Food and Drugs Administration (FDA) for approval. BCOs are formalised in the standard IEEE 2791-2020 [53] as a combination of [JSON Schemas](#) that define the structure of JSON metadata files describing exemplar workflow runs in detail, covering aspects such as the usability and error domain of the workflow, its runtime requirements, the reference datasets used and representative output data produced.

BCOs provide a structured view over a particular workflow, informing regulators about its workings independently of the underlying workflow definition language. However, BCOs have only limited support for additional metadata. For instance, while the BCO itself can indicate authors and contributors, and in particular regulators and their review decisions, it cannot describe the provenance of individual data files or workflow definitions.

As a custom JSON format, BCOs cannot be extended with Linked Data concepts, except by adding an additional top-level JSON object formalised in another JSON Schema. A BCO and workflow submitted by upload to a regulator will also frequently consist of multiple cross-related files. Crucially, there is no way to tell whether a given `*.json` file is a BCO file, except by reading its content and check for its `spec_version`.

We can then consider how a BCO and its referenced artefacts can be packaged and transferred following FAIR principles. [BCO RO-Crate](#), part of the BioCompute Object user guides, defines a set of best practices for wrapping a BCO within a workflow, together with its exemplar outputs in an RO-Crate, which then provides typing and additional provenance metadata of the individual files, workflow definition, referenced data and the BCO metadata itself. While the BCO remains rigid, the RO-Crate is more open-ended and can therefore also describe other files in the submission not directly related to the BCO, such as further workflow documentation.

While there is some overlap in that RO-Crate can also describe a computational workflow, as detailed in previous sections, a *separation of concerns* emerges, where the BCO is responsible for describing

the inside of a workflow and its run at an abstraction level suitable for a domain scientist, while the RO-Crate describes the surroundings of the workflow, classifying and relating its resources and providing provenance of their existence beyond the BCO.

A similar separation of concerns can be found within the RO-Crate itself, where the transport-level metadata, such as checksum of files, are [delegated to BagIt](#) manifests, a standard focusing on the preservation challenges of digital libraries[12]. As such, RO-Crates are not required to list all the files in their folder hierarchy, but only those that are deemed to be need a description.

Specifically, a BCO alone is insufficient for reliable re-execution of a workflow, which would need a compatible workflow engine depending on the workflow definition language, so IEEE 2791 recommends using Common Workflow Language [54] for interoperable pipeline execution. CWL itself relies on tool packaging in software containers using Docker or Conda. Thus, we can consider BCO-RO-Crate as a stack consisting of transport-level manifests of files (BagIt), provenance, typing and context of those files (RO-Crate), workflow overview and purpose (BCO), interoperable workflow definition (CWL) and tool distribution (Docker).

Separation of Concerns in BCO RO-Crate. BioCompute Object (IEEE2791) is a JSON file that structurally explains the purpose and implementation of a computational workflow, for instance implemented in Nextflow, that installs the workflow's software dependencies as Docker containers or BioConda packages. An example execution of the workflow shows the different kinds of result outputs, which may be external, using GitHub LFS to support larger data. RO-Crate gathers all these local and external resources, relating them and giving individual descriptions, for instance permanent DOI identifiers for reused datasets accessed from Zenodo, but also adding external identifiers to attribute authors using ORCID or to identify which licenses apply to individual resources. The RO-Crate and its local files are captured in a BagIt whose checksum ensures completeness, combined with Big Data Bag [55] features to "complete" the bag with large external files such as the workflow outputs

Digital Humanities: Cultural Heritage

[PARADISEC](#) (the Pacific And Regional Archive for Digital Sources in Endangered Cultures) maintains a repository of more than 500,000 files documenting endangered languages across more than 16,000 items, collected over many years by researchers interviewing and recording native speakers across the region. As a proposed update of the 18 year old infrastructure, the [Modern PARADISEC](#)

[demonstrator](#) has been [developed](#) to also help digitally preserve these artefacts using the [Oxford Common File Layout](#) (OCFL) for file consistency and RO-Crate for structuring and capturing the metadata of each item. The existing PARADISEC data collection has been ported and captured as RO-Crates. A web portal then exposes the repository and its entries by indexing the RO-Crate metadata files using Elasticsearch as a “NoSQL” object database, presenting a domain-specific view of the items - the RO-Crate is “hidden” and does not change the user interface.

This use case takes advantage of several RO-Crate features and principles. Firstly, the transcribed metadata is now independent of the PARADISEC platform and can be archived, preserved and processed in its own right, using Schema.org vocabularies augmented with PARADISEC-specific terms. The lightweight infrastructure with RO-Crate as the holder of itemised metadata in regular files (organized using OCFL[13], with checksums for integrity checking and versioning) also gives flexibility for future developments and maintenance; for example, potentially using Linked Data software such as a graph database, queried using SPARQL triple patterns across RO-Crates, or a “last resort” fallback to the generic RO-Crate HTML preview [31], which can be hosted as static files by any web server, in line with the approach taken by the Endings Project².

Machine-actionable Data Management Plans

Machine-actionable Data Management Plans (maDMPs) have been proposed as an improvement to automate FAIR data management tasks in research [56], e.g., by using PIDs and controlled vocabularies to describe what happens to data over the research life cycle. The Research Data Alliance’s *DMP Common Standard* for maDMPs [57] is one such formalisation for expressing maDMPs, which can be expressed as Linked Data using the DMP Common Standard Ontology [58], a specialization of the W3C Data Catalog Vocabulary (DCAT) [59]. RDA maDMPs are usually expressed using regular JSON, conforming to the DMP JSON Schema.

A mapping has been produced between Research Object Crates and Machine-actionable Data Management Plans [45], implemented by the RO-Crate {RDA maDMP Mapper [44]. A similar mapping has been implemented by RO-Crate_2_ma-DMP [46]. In both cases, a maDMP can be converted to a RO-Crate, or vice versa. In [45] this functionality caters for two use cases:

1. Start a skeleton data management plan based on an existing RO-Crate dataset, e.g. from an RO-Crate from WorkflowHub.
2. Instantiate an RO-Crate based on a data management plan.

An important difference here is that data management plans are (ideally) written in advance of data production, while RO-Crates are typically created to describe data after it has been generated. This approach shows the importance of *templating* to make both tasks more automatable and achievable, and how RO-Crate can fit into earlier stages of the research life cycle.

Institutional data repositories – Harvard Data Commons

Related Work

With the increasing digitization of research processes, there has been a significant call for the wider use of interoperable sharing of data and its associated metadata. For a comprehensive overview of this literature and recommendations in particular for data, we refer to [60], which highlights the wide variety of metadata and documentation that the literature prescribes for enabling the reuse of data.

Here, instead of surveying the large literature on sharing digital scholarly artefacts, we rather focus on approaches to bundling such artefacts along with their metadata. This notion has a long history [61], but recent approaches have followed three strands: 1) publishing to centralised repositories; 2) packaging approaches similar to RO-Crate; and 3) bundling the computational workflow around a scientific experiment.

Bundling and Packaging Digital Research Artefacts

The challenge of describing computational workflows was one of the main motivations for the early proposal of *Research Objects* [9] as first-class citizens for sharing and publishing, by bundling datasets, workflows, scripts and results along with traditional dissemination materials like journal articles and presentations, forming a single package. Crucially, these resources are not just gathered, but also individually typed, described and related to each-other using semantic vocabularies. As pointed out in [9] an open-ended *Linked Data* approach is not sufficient for scholarly communication, as a common data model is also needed in addition to common practices for managing and annotating lifecycle, ownership, versioning and attributions.

Considering the FAIR principles, we can say with hindsight that the initial Research Objects approaches strongly targeted *Interoperability*, with a particular focus on reproducibility with computational workflows and reuse of existing RDF vocabularies.

The first implementation of Research Objects in 2009 for sharing workflows in myExperiment [62] was based on RDF ontologies [63], building on Dublin Core, FOAF, SIOC, Creative Commons, OAI-ORE and (later) DBpedia to form myExperiment ontologies for describing social networking, attribution and credit, annotations, aggregation packs, experiments, view statistics, contributions, and workflow components. [64]

Programmatic access to Research Objects was facilitated with an RDF endpoint that exposed individual myExperiment resources, also queryable from a SPARQL endpoint, both using the myExperiment vocabularies and RDF formats RDF/XML and Turtle.

FAIR Digital Objects

FAIR Digital Objects (FDO) [65] have been proposed as a conceptual framework for making digital resources available in a Digital Objects (DO) architecture that encourages active use of the objects and their metadata. In particular, an FDO has five parts: (i) The FDO *content*, bit sequences stored in an accessible repository; (ii) a *Permanent Identifier* (PID) such as a DOI that identifies the FDO and can resolve these parts; (iii) Associated rich *metadata*, as separate FDOs; (iv) Type definitions, also separate FDOs; (v) Associated *operations* for the given types. A Digital Object typed as a Collection aggregates other DOs by reference.

As an “[abstract protocol](#)”, Digital Objects could be implemented in multiple ways. One suggested implementation is the [FAIR Digital Object Framework](#), based on HTTP and the Linked Data Principles. While there is agreement on using permanent identifiers based on DOI, consensus on how to represent common metadata, core types and collections as FDOs has not yet been reached. We argue that RO-Crate can play an important role for FDOs:

1. By providing a predictable and extensible serialization of structured metadata.
2. By formalizing how to aggregate digital objects as a collection (and adding their context).
3. By providing a natural Metadata FDO in the form of the RO-Crate Metadata File.

4. By being based on Linked Data and schema.org vocabulary, meaning that PIDs already exist for common types and properties.

At the same time it is clear that the goal of FDO is broader than that of RO-Crate; namely FDOs are active objects with distributed operations, and add further constraints such as permanent identifiers for every element. These features improve FAIR features of digital objects and are also useful for RO-Crate, but they also severely restrict the possible FDO infrastructure that needs to be implemented and maintained in order for FDOs to remain available. RO-Crate, on the other hand, is more flexible: it can minimally be used within any file system structure, or ideally exposed through a range of Web-based scenarios. A *FAIR profile of RO-Crate* (e.g. enforcing PID usage) will fit well within a FAIR Digital Object ecosystem.

Packaging Workflows

The use of computational workflows has gained prominence, in particular in the life sciences, typically combining a chain of open source tools in an analytical pipeline. While workflows may have initially been used to improve scalability, it can be argued that they also assist in making computed data results FAIR. At the same time, however, they raise additional FAIR challenges, since they can be considered as important research artefacts themselves, posing the problem of capturing and explaining the computational methods behind the analysis [66].

Even when researchers follow current best practice for workflow reproducibility, [67] [68] the communication of outcomes through traditional academic publishing routes with a textual representation adds barriers that hinder reproducibility and FAIR use of the knowledge previously captured in the workflow.

As a real-life example, let's look at a metagenomics article [69] where the authors have gone to extraordinary efforts to document the individual tools that have been reused, including their citations, versions, settings, parameters and combinations. The *Methods* section is 2 pages in tight double-columns with 24 additional references, supported by data availability on an FTP server (60 GB) [70] and the open source code available in GitHub [Finn-Lab/MGS-gut](#) [71] including the pipeline as shell scripts, and associated analysis scripts in R and Python.

This attention to reporting detail for computational workflows is unfortunately not yet the norm, and although bioinformatics journals have strong *data availability* requirements, they frequently do not require authors to include or cite *software, scripts and pipelines* used for analysing and producing results [72] – rather, authors might be penalised for doing so [cite?] as it would detrimentally count against arbitrary limits on number of pages and references.

However detailed this additional information might be, another researcher who wants to reuse a particular computational method may first want to assess if the described tool and workflow is Re-runnable (executable at all), Repeatable (same results for original inputs on same platform), Reproducible (same results for original inputs with different platform or newer tools) and ultimately Reusable (similar results for different input data), Repurposable (reusing parts of the method for making a new method) or Replicable (rewriting the workflow following the method description). [73] [74]

Following the textual description alone, researchers would be forced to jump straight to evaluate “Replicable” by rewriting the pipeline from scratch. This can be expensive and error-prone. They would firstly need to install all the software dependencies and reference datasets. This can be a daunting task in and of itself, which may have to be repeated multiple times as workflows typically are developed at small scale on desktop computers, scaled up to local clusters, and potentially

productionized using cloud instances, each of which will have different requirements for software installations.

In recent years the situation has been greatly improved by software packaging and container technologies like Docker and Conda, which have seen increased adaptation in life sciences [75], with supporting collaborative efforts like BioConda [76], BioContainers [77] and by Linux distributions themselves (e.g. Debian Med [78]), to make more than 7000 software packages available [in BioConda alone] (<https://anaconda.org/bioconda/>) and 9000 containers [in BioContainers](#). Docker and Conda have gained integration in workflow systems like Snakemake, Galaxy, Nextflow, meaning a downloaded workflow definition can now be executed on a “blank” machine (except for the workflow engine) with the underlying analytical tools installed on demand.

Conclusion

RO-Crate provides a lightweight approach to packaging digital research artefacts with structured metadata, assisting developers and researchers to produce and consume FAIR data archives of their Research Objects, including permanent identifiers, context and provenance of research items. Aggregated data may be large and distributed, or regular folders on a file system.

As a set of Best Practice recommendations, developed by an open and broad community, RO-Crate shows how to use “just enough” Linked Data standards in a consistent way, with structured metadata using a rich base vocabulary that can cover everyday contextual relations, whilst retaining extensibility to domain- and application-specific uses.

RO-Crate is supported by multiple open source tools and libraries, fits into the larger landscape of open scholarly communication and FAIR Digital Object infrastructure, and can be easily integrated into data repository platforms. RO-Crate can be applied as a data/metadata exchange mechanism, assist in long-term archival preservation of metadata and data, or simply used at small-scale by individual researchers.

Formalizing RO-Crate in First Order Logic

Below is an attempt to formalize the concept of RO-Crate as a set of relations using First Order Logic:

Language

```
 $\mathbb{L}_{ro-crate} = \{ \text{Property}(p), \text{Class}(c), \text{Literal}(x), \mathbb{R}, \mathbb{S} \}$   
 $\mathbb{D} = \mathbb{Iri}$   
 $\mathbb{Iri} \equiv \{ \text{IRIs as defined in RFC3987} \}$   
 $\mathbb{R} \equiv \{ \text{real or integer numbers} \}$   
 $\mathbb{S} \equiv \{ \text{literal strings} \}$ 
```

The domain of discourse is the set of \mathbb{Iri} identifiers [15] (notation `<http://example.com/>`), with additional descriptions using numbers \mathbb{R} (notation `13.37`) and literal strings \mathbb{S} (notation `"Hello"`).

From this formalized language $\mathbb{L}_{ro-crate}$ an RO-Crate can be interpreted in any representation that can gather these descriptions, their properties, classes, and literal attributes.

Minimal RO-Crate

Below is using $\mathbb{L}_{ro-crate}$ to define a minimal RO-Crate:

$$\begin{aligned}
\text{RO-Crate}(R) \models & \text{Root}(R) \wedge \text{Mentions}(R, R) \wedge \\
& \text{hasPart}(R, d) \wedge \text{Mentions}(R, d) \wedge \text{DataEntity}(d) \wedge \\
& \text{Mentions}(R, c) \wedge \text{ContextualEntity}(c) \\
\forall r \text{ Root}(r) \rightarrow & \text{Dataset}(r) \wedge \text{name}(r, n) \wedge \text{description}(r, d) \\
& \wedge \text{published}(r, \text{date}) \wedge \text{license}(e, l) \\
\forall e \forall n \text{ name}(e, n) \rightarrow & \text{Literal}(n) \\
\forall e \forall d \text{ description}(e, d) \rightarrow & \text{Literal}(d) \\
\forall e \forall \text{date} \text{ datePublished}(e, \text{date}) \rightarrow & \text{Literal}(\text{date}) \\
\forall e \forall l \text{ license}(e, l) \rightarrow & \text{ContextualEntity}(l) \\
\text{DataEntity}(e) \equiv & \text{File}(e) \oplus \text{Dataset}(e) \\
\text{Entity}(e) \equiv & \text{DataEntity}(e) \vee \text{ContextualEntity}(e) \\
\forall e \text{ Entity}(e) \rightarrow & \text{Class}(e) \\
\text{Mentions}(R, s) \models & \text{Relation}(s, p, e) \oplus \text{Attribute}(s, p, l) \\
\text{Relation}(s, p, o) \models & \text{Entity}(s) \wedge \text{Property}(p) \wedge \text{Entity}(o) \\
\text{Attribute}(s, p, x) \models & \text{Entity}(s) \wedge \text{Property}(p) \wedge \text{Literal}(x) \\
\text{Literal}(x) \equiv & x \in \mathbb{R} \oplus x \in \mathbb{S}
\end{aligned}$$

An `RO-Crate(R)` is defined as a self-described *Root Data Entity*, which describes and contains parts (*data entities*), which are further described in *contextual entities*. These terms align with their use in the [RO-Crate 1.1 terminology](#).

The `Root(r)` is a type of `Dataset(r)`, and must have the metadata to literal attributes to provide a `name`, `description` and `datePublished`, as well as a contextual entity identifying its license. These predicates correspond to the RO-Crate 1.1 [requirements for the root data entity](#).

The concept of an `Entity(e)` is introduced as being either a `DataEntity(e)`, a `ContextualEntity(e)`, or [both](#); and must be typed with at least one `Class(e)`.

For simplicity in this formalization (and to assist production rules below) `R` is a constant representing a single RO-Crate, typically written to independent RO-Crate Metadata files. `R` is used by `Mentions(R, e)` to indicate that `e` is an Entity described by the RO-Crate and therefore its metadata (a set of Relation and Attribute predicates) form part of the RO-Crate serialization. `Relation(s, p, o)` and `Attribute(s, p, x)` are defined as a *subject-predicate-object* triple pattern from an `Entity(s)` using a `Property(p)` to either another `Entity(o)` or a `Literal(x)` value.

Example of formalized RO-Crate

The below is an example RO-Crate represented using the above formalization, assuming a base URI of `http://example.com/ro/123/`:

```

RO-Crate(<http://example.com/ro/123/>)
name(<http://example.com/ro/123/,
    "Data files associated with the manuscript:Effects of ...")
description(<http://example.com/ro/123/,
    "Palliative care planning for nursing home residents ...")
datePublished(<http://example.com/ro/123/>, "2017")
license(<http://example.com/ro/123/>,
    <https://creativecommons.org/licenses/by-nc-sa/3.0/au/>
ContextualEntity(<https://creativecommons.org/licenses/by-nc-sa/3.0/au/>)
name(<https://creativecommons.org/licenses/by-nc-sa/3.0/au/,
    "Attribution-NonCommercial-ShareAlike 3.0 Australia (CC BY-NC-SA 3.0
AU)")

hasPart(<http://example.com/ro/123/>, <http://example.com/ro/123/file.txt>)
File(<http://example.com/ro/123/survey.csv>)
name(<http://example.com/ro/123/survey.csv>, "Survey of care providers")
hasPart(<http://example.com/ro/123/>,
    <http://www.example.com/ro/123/folder/>)
Dataset(<http://example.com/ro/123/interviews/>)
name(<http://example.com/ro/123/interviews/>,
    "Audio recordings of care provider interviews")

```

In reality many additional attributes from schema.org types like <http://schema.org/Dataset> and <http://schema.org/CreativeWork> would be used to further describe the RO-Crate and its entities, but as these are optional they do not form part of this formalization.

Mapping to RDF with schema.org

A formalized RO-Crate can be mapped to different serializations. Below follows a mapping to RDF using schema.org.

```

Dataset(d) → type(d, <http://schema.org/Dataset>)
File(f) → type(f, <http://schema.org/MediaObject>)
Property(p) → type(p, <http://www.w3.org/2000/01/rdf-schema#Property>)
Class(c) → type(c, <http://www.w3.org/2000/01/rdf-schema#Class>)
CreativeWork(e) → ContextualEntity(e) ∧ type(e,
    <http://schema.org/CreativeWork>)
hasPart(e, t) → Relation(e, <http://schema.org/hasPart>, t)
type(e, t) → Relation(e, <http://www.w3.org/1999/02/22-rdf-syntax-ns#type>,
    t) ∧ Class(t)
name(e, n) → Attribute(e, <http://schema.org/name>, n)
description(e, d) → Attribute(e, <http://schema.org/description>, d)
datePublished(e, date) → Attribute(e, <http://schema.org/datePublished>,
    date)
license(e, l) → Relation(e, <http://schema.org/license>, l) ∧
CreativeWork(l)

```

Note that in the JSON-LD serialization of RO-Crate the expression of `Class` and `Property` is typically indirect, as the JSON-LD `@context` maps to schema.org IRIs, which when resolved as Linked Data embeds their formal definition as RDFa.

RO-Crate 1.1 Metadata File Descriptor

An important RO-Crate principle is that of being **self-describing**. Therefore the serialization of the RO-Crate into a file should also describe itself in a [Metadata File Descriptor](#), indicating it is about (describing) the RO-Crate root data entity, and that it conforms to a particular version of the RO-Crate specification:

```
about(s,o) → Relation(s, <http://schema.org/about>, o)
conformsTo(s,o) → Relation(s, <http://purl.org/dc/terms/conformsTo>, R)
MetadataFileDescriptor(m) → ( CreativeWork(m) ∧ about(m,R) ∧ RO-Crate(R) ∧
    conformsTo(m, <https://w3id.org/ro/crate/1.1>) )
```

Note that although the metadata file necessarily is an *information resource* written to disk or served over the network (e.g. as JSON-LD), it is not considered to be a contained *part* of the RO-Crate in the form of a *data entity*, rather it is described only as a *contextual entity*.

While in the conceptual model the *RO-Crate Metadata File* can be seen as the top-level node that describes the *RO-Crate Root*, in the formal model (and the JSON-LD format) the metadata file descriptor is an additional contextual entity and not affecting the depth-limit of the RO-Crate.

Forward-chained Production Rules for JSON-LD

Combining the above predicates and schema.org mapping with rudimentary JSON templates, these forward-chaining production rules can output JSON-LD according to the RO-Crate 1.1 specification³:

```
Mentions(R, s) ∧ Relation(s, p, o) → Mentions(R, o)
i ∈ Iiri → "i"
r ∈ R → r
s ∈ S → "s"
∀s∀p∀o Relation(s,p,o) → { "@id": s,
                             p: { "@id": o }
                           }
∀s∀p∀v Attribute(s,p,v) → { "@id": s,
                             p: v
                           }
∀r∀c RO-Crate(r) → { "@graph": [ Mentions(r, c)* ] }
R ⊨ <./>
MetadataFileDescriptor(<ro-crate-metadata.json>)
```

This exposes the first order logic domain of discourse of IRIs, with rational numbers and strings as their corresponding JSON-LD representation. These production rules first grow the graph of `R` by adding a transitive rule that anything described in `R` which is related to `o` means that `o` is also mentioned by the RO-Crate `R`. For simplicity this rule is one-way; in practice the JSON-LD graph can

also contain free-standing contextual entities that have outgoing relations to data- and contextual entities.

Steffen Möller, Stuart W. Prescott, Lars Wirzenius, Petter Reinholdtsen, Brad Chapman, Pjotr Prins, Stian Soiland-Reyes, Fabian Klötzl, Andrea Bagnacani, Matúš Kalaš, ... Michael R. Crusoe
Data Science and Engineering (2017-11-16)

DOI: [10.1007/s41019-017-0050-4](https://doi.org/10.1007/s41019-017-0050-4)

76. Bioconda: sustainable and comprehensive software distribution for the life sciences.

Björn Grüning, Ryan Dale, Andreas Sjödin, Brad A Chapman, Jillian Rowe, Christopher H Tomkins-Tinch, Renan Valieris, Johannes Köster, Bioconda Team

Nature Methods (2018)

DOI: [10.1038/s41592-018-0046-7](https://doi.org/10.1038/s41592-018-0046-7) · PMID: [29967506](https://pubmed.ncbi.nlm.nih.gov/29967506/)

77. BioContainers: an open-source and community-driven framework for software standardization.

Felipe da Veiga Leprevost, Björn A Grüning, Saulo Alves Aflitos, Hannes L Röst, Julian Uszkoreit, Harald Barsnes, Marc Vaudel, Pablo Moreno, Laurent Gatto, Jonas Weber, ... Yasset Perez-Riverol
Bioinformatics (2017-08-15)

DOI: [10.1093/bioinformatics/btx192](https://doi.org/10.1093/bioinformatics/btx192) · PMID: [28379341](https://pubmed.ncbi.nlm.nih.gov/28379341/) · PMCID: [PMC5870671](https://pubmed.ncbi.nlm.nih.gov/PMC5870671/)

78. Community-driven computational biology with Debian Linux.

Steffen Möller, Hajo Nils Krabbenhöft, Andreas Tille, David Paleino, Alan Williams, Katy Wolstencroft, Carole Goble, Richard Holland, Dominique Belhachemi, Charles Plessy
BMC Bioinformatics (2010-12-21)

DOI: [10.1186/1471-2105-11-s12-s5](https://doi.org/10.1186/1471-2105-11-s12-s5) · PMID: [21210984](https://pubmed.ncbi.nlm.nih.gov/21210984/) · PMCID: [PMC3040531](https://pubmed.ncbi.nlm.nih.gov/PMC3040531/)

79. Beyond authorship: attribution, contribution, collaboration, and credit

Amy Brand, Liz Allen, Micah Altman, Marjorie Hlava, Jo Scott

Learned Publishing (2015-04-01) <https://doi.org/gc6v3m>

DOI: [10.1087/20150211](https://doi.org/10.1087/20150211)

-
1. IRIs^[15] are a generalisation of URIs (which include well-known http/https URLs), permitting international Unicode characters without % -encoding, commonly used on the browser address bar and in HTML5.↵
 2. The [Endings Project](#) is a five-year project funded by the Social Sciences and Humanities Research Council (SSHRC) that is creating tools, principles, policies and recommendations for digital scholarship practitioners to create accessible, stable, long-lasting resources in the humanities.↵

3. Limitations: The full list of types, relations and attribute properties from the RO-Crate specification are not included. Examples shown include `datePublished`, `CreativeWork` and `name`. Contextual entities not related from the RO-Crate (e.g. using inverse relations to a data entity) would not be covered by the single direction `Mentions(R, s)` production rule; see [issue #122](#). The `datePublished(e, date)` rule do not include syntax checks for the ISO 8601 datetime format. Compared with RO-Crate examples, this generated JSON-LD does not use a `@context` as the IRIs are produced unshortened; a post-step could do JSON-LD Flattening with a versioned RO-Crate context.[↩](#)
